

This study examines the relationship between students who take dual credit and / or advanced placement (AP) in high school and their college academic performance and first-year retention.

Holding ability indicators constant, students entering college with AP tend to get higher first-year GPA's than those students entering college with dual credit only or than those students entering college with no college credit. However, students who entered with AP or dual credit both returned for their second year at a higher rate than students who entered with no college credit.

Across the nation, there is an increasing demand for dual credit courses that are taught by high school teachers in the high school for college and high school credit. Proponents of these programs claim positive results (Peterson, Anjewierden, & Corser, 2001). Students benefit by completing college in less time, spending less money, and becoming prepared for the demands of post-secondary education while still in high school (Hanson, 2001). At the same time, colleges realize benefits in the form of a way to recruit students (Hugo, 2001), increase visibility, and gain an important engagement function (AASCU, 2002). However, relatively few studies have examined how well students with dual credit and/or advanced credit do in college—when academic ability is controlled—in contrast to students who enter with no college credit.

Three research questions are addressed in this study. When controlling for academic ability:

1. Is there a difference in first-year college grade point average (GPA) between students who had no prior advanced placement (AP) or dual credit in contrast to students who did receive credit in AP or dual-credit courses?
2. Is there a difference in first-year college retention between students who entered college with no college credit in contrast to students who entered college with dual credit or AP credits?
3. Does the source of dual credit courses have any relationship to first-year college GPA or retention?

credit students are identified as students, while in high school, that take college courses taught by high school teachers at the high school.

Based on first-year performances (Table 1), it appears that students coming in with AP only or both AP and Dual credit do better (3.28 and 3.32 GPA, respectively) and earn more hours (43 and 41) than other students by the end of their first year of college work. Students having some dual high school work also appear to do better than those coming in with no previous college work, 2.92 versus 2.70. However, it also appears that those with dual credit come in with higher high school percentile ranks and ACT scores than those without any previous AP or dual credit experience. Therefore, the first research question was to determine if these differences remain if one holds student ability (based on high school rank, ACT test scores, and completion of Missouri's high school core curriculum.

AP Only	505	29.1	84	3.28	43
Dual High School Only	3,135	25.8	82	2.92	42
Both AP and Dual	300	29.3	89	3.32	52
No College Credit	3,973	24.7	73	2.70	30

\* Grades in the dual credit courses were not included in the first-year GPA calculation.

Holding entering academic ability constant (ACT = 26, HS Rank = 85), students with AP only have the highest predicted GPA (3.18) followed by students with both AP and dual credit (3.14). Those students entering with no previous college credit and those students entering with dual credit courses only had the same predicted GPA (2.97).

There was a distinct difference in terms of the return rate between those with some and those without any AP or dual credit (Table 4). Of those with only AP credit, 87% returned for their second academic year compared to the return rates of those students who entered with both AP and dual credit (90%) or dual credit only (89%). Students who entered with no previous college credit returned at a rate of 76%.

The overall logistic regression model was statistically significant and six independent variables contributed to the model: dual credit only (point estimate = +2.2), both dual and AP credit (pe =+1.8), AP credit only (pe = +1.6), completed HS core (pe = +1.7), ACT (pe = +1.05), and HS rank (pe = +1.01). The logistic regression model enabled us to predict 65% cases correctly. Holding academic ability constant, students entering college with only dual credit, only AP credit, or AP and dual credit, had an increased likelihood of returning to college compared to those students who entered with no college credit.

Point estimates can be interpreted in the following manner. Holding the measures of student ability constant, for example, the odds of a student returning for the fall semester who entered his or her first year with only AP credit would be 56.6% ( $1.566 - 1 = 56.6\%$ ) more likely than a student who began his or her freshman year with no college credit. Alternatively, again holding ability measures constant, students who enter with both dual credit and AP credit would be 83.6% ( $1.836 - 1 = 83.6\%$ ) more likely to return the following fall than those who enter with no college credit.

To address this research question, students who received their dual credit from more than one type of institution were removed from the analysis. Furthermore, the source of dual credit was divided into four categories: those students who received their dual credit from System Campus A, System Campus B, all other four-year institutions in the state, and all two-year institutions in the state.

Those getting dual credit at Missouri two-year institutions have a higher average ACT score (26.2) as well as higher high school percentile rank, on average, than students getting dual credit at Missouri four-year institutions or at one of the System campuses. However, those getting all their dual credit at two-year institutions tend to have a lower end of first-year GPA than the others.

In order to determine if the GPA difference was caused by difference in student abilities, linear regression was used. The model was statistically significant and explained 24.8% of the variance in first-year GPA. The majority of the variance in the model was explained by two measures of academic ability: ACT Composite score and high school percentile rank. However, the type of institution from which the dual credit was earned did contribute to the model. Holding academic ability constant, we were interested in knowing whether students who entered with dual

Student Characteristics held constant: ACT = 26 and HS Rank = 85

student characteristics and first semester GPA (in contrast to the academic year GPA). Further, it may have been more logical to have examined fall semester to spring semester retention (in contrast to second academic year retention). This third limitation is related to the idea that the “treatment” (e.g., taking dual credit or AP courses in high school) should be as close to the “measure” (e.g., first-year GPA, retention) as possible. Fourth, the regression models, although statistically significant, did not explain an overwhelmingly majority of the variance.

First, when holding academic ability constant, students earning dual credit while in high school do not appear to do significantly better than other students who enter college with no dual credit. At the same time, students who take dual credit do not appear to do worse than students who enter with no previous college credit. Additionally, students entering with dual credit and/or AP were more likely to return to college the second year than other students having earned no dual credit. This finding may be of interest to college recruiters in that it suggests that students who enter with college credit tend to return for their second year. Lastly, the source of the dual credit may make some difference in terms of their academic performance during the first year. Those earning dual credit at a two-year institution tended to get lower first-year GPA's than those earning their dual credit at other institutions. This finding could, however, be a result of other factors. Many of the two-year colleges who offered dual credit in this study tend to have a fairly high concentration of dual credit students in rural settings. Thus, the transition from the rural setting to a four-year university may have also played a role in lower expected first-year GPAs. Having said that, however, the source of dual credit did not make any detectable difference in a student's likelihood of returning for the second year.

Many of the findings in this study mirror the key findings in a study conducted at Saint Louis University (Delicath, 1999). Dual credit hours earned, as well as AP credit earned, were found to be positively correlated with the likelihood of the student returning for the second year. Furthermore, Delicath (1999) found that dual credit and AP credit was positively correlated with time-to-graduation and graduating within five years. In addition to replicating this study in other settings, further research should explore whether students who enter college with advanced standing use this advanced standing to enhance and fortify their college experience. Are these students more likely to get engaged in college? Are they more likely to get involved in educational purposeful activities such as student organizations, research projects with faculty members, studies abroad, leadership opportunities, and so forth? Or, do students who enter college with advanced standing tend to be less engaged in their college experience and pursue activities that may not necessarily enhance their college experience (e.g., spending more hours working, etc.)? Addressing these types of questions would certainly contribute to our understanding of the role that dual credit and related programs have on college students specifically and on colleges and universities in general.
